

Core DOM

A Formal Model of the Document Object Model

Abstract

In this AFP entry, we formalize the core of the Document Object Model (DOM). At its core, the DOM defines a tree-like data structure for representing documents in general and HTML documents in particular. It is the heart of any modern web browser.

Formalizing the key concepts of the DOM is a prerequisite for the formal reasoning over client-side JavaScript programs and for the analysis of security concepts in modern web browsers.

We present a formalization of the core DOM, with focus on the *node-tree* and the operations defined on node-trees, in Isabelle/HOL. We use the formalization to verify the functional correctness of the most important functions defined in the DOM standard. Moreover, our formalization is 1. *extensible*, i.e., can be extended without the need of re-proving already proven properties and 2. *executable*, i.e., we can generate executable code from our specification.

Keywords: Document Object Model, DOM, Formal Semantics, Isabelle/HOL

1 Introduction

In a world in which more and more applications are offered as services on the internet, web browsers start to take on a similarly central role in our daily IT infrastructure as operating systems. Thus, web browsers should be developed as rigidly and formally as operating systems. While formal methods are a well-established technique in the development of operating systems (see, e.g., Klein [12] for an overview of formal verification of operating systems), there are few proposals for improving the development of web browsers using formal approaches [2, 9, 10, 13].

As a first step towards a verified client-side web application stack, we model and formally verify the Document Object Model (DOM) in Isabelle/HOL. The DOM [14, 15] is *the* central data structure of all modern web browsers. At its core, the Document Object Model (DOM), defines a tree-like data structure for representing documents in general and HTML documents in particular. Thus, the correctness of a DOM implementation is crucial for ensuring that a web browser displays web pages correctly. Moreover, the DOM is the core data structure underlying client-side JavaScript programs, i. e., client-side JavaScript programs are mostly programs that read, write, and update the DOM.

In more detail, we formalize the core DOM as a shallow embedding [11] in Isabelle/HOL. Our formalization is based on a typed data model for the *node-tree*, i. e., a data structure for representing XML-like documents in a tree structure. Furthermore, we formalize a typed heap for storing (partial) node-trees together with the necessary consistency constraints. Finally, we formalize the operations (as described in the DOM standard [15]) on this heap that allow manipulating node-trees.

Our machine-checked formalization of the DOM node tree [15] has the following desirable properties:

- It provides a *consistency guarantee*. Since all definitions in our formal semantics are conservative and all rules are derived, the logical consistency of the DOM node-tree is reduced to the consistency of HOL.
- It serves as a *technical basis for a proof system*. Based on the derived rules and specific setup of proof tactics over node-trees, our formalization provides a generic proof environment for the verification of programs manipulating node-trees.
- It is *executable*, which allows to validate its compliance to the standard by evaluating the compliance test suite on the formal model and
- It is *extensible* in the sense of [3, 7], i. e., properties proven over the core DOM do not need to be re-proven for object-oriented extensions such as the HTML document model.

The rest of this document is automatically generated from the formalization in Isabelle/HOL, i.e., all content is checked by Isabelle.¹ The structure follows the theory dependencies (see Figure 1.1): we start with introducing the technical preliminaries of our formalization (chapter 2). Next, we introduce the concepts of pointers (chapter 3) and classes (chapter 4), i.e., the core object-oriented datatypes of the DOM. On top of this data model, we define the functional behavior of the DOM classes, i.e., their methods (chapter 5). In chapter 6, we introduce the formalization of the functionality of the core DOM, i.e., the *main entry point for users* that want to use this AFP entry. Finally, we formalize the relevant compliance test cases in chapter 7.

¹For a brief overview of the work, we refer the reader to [4].

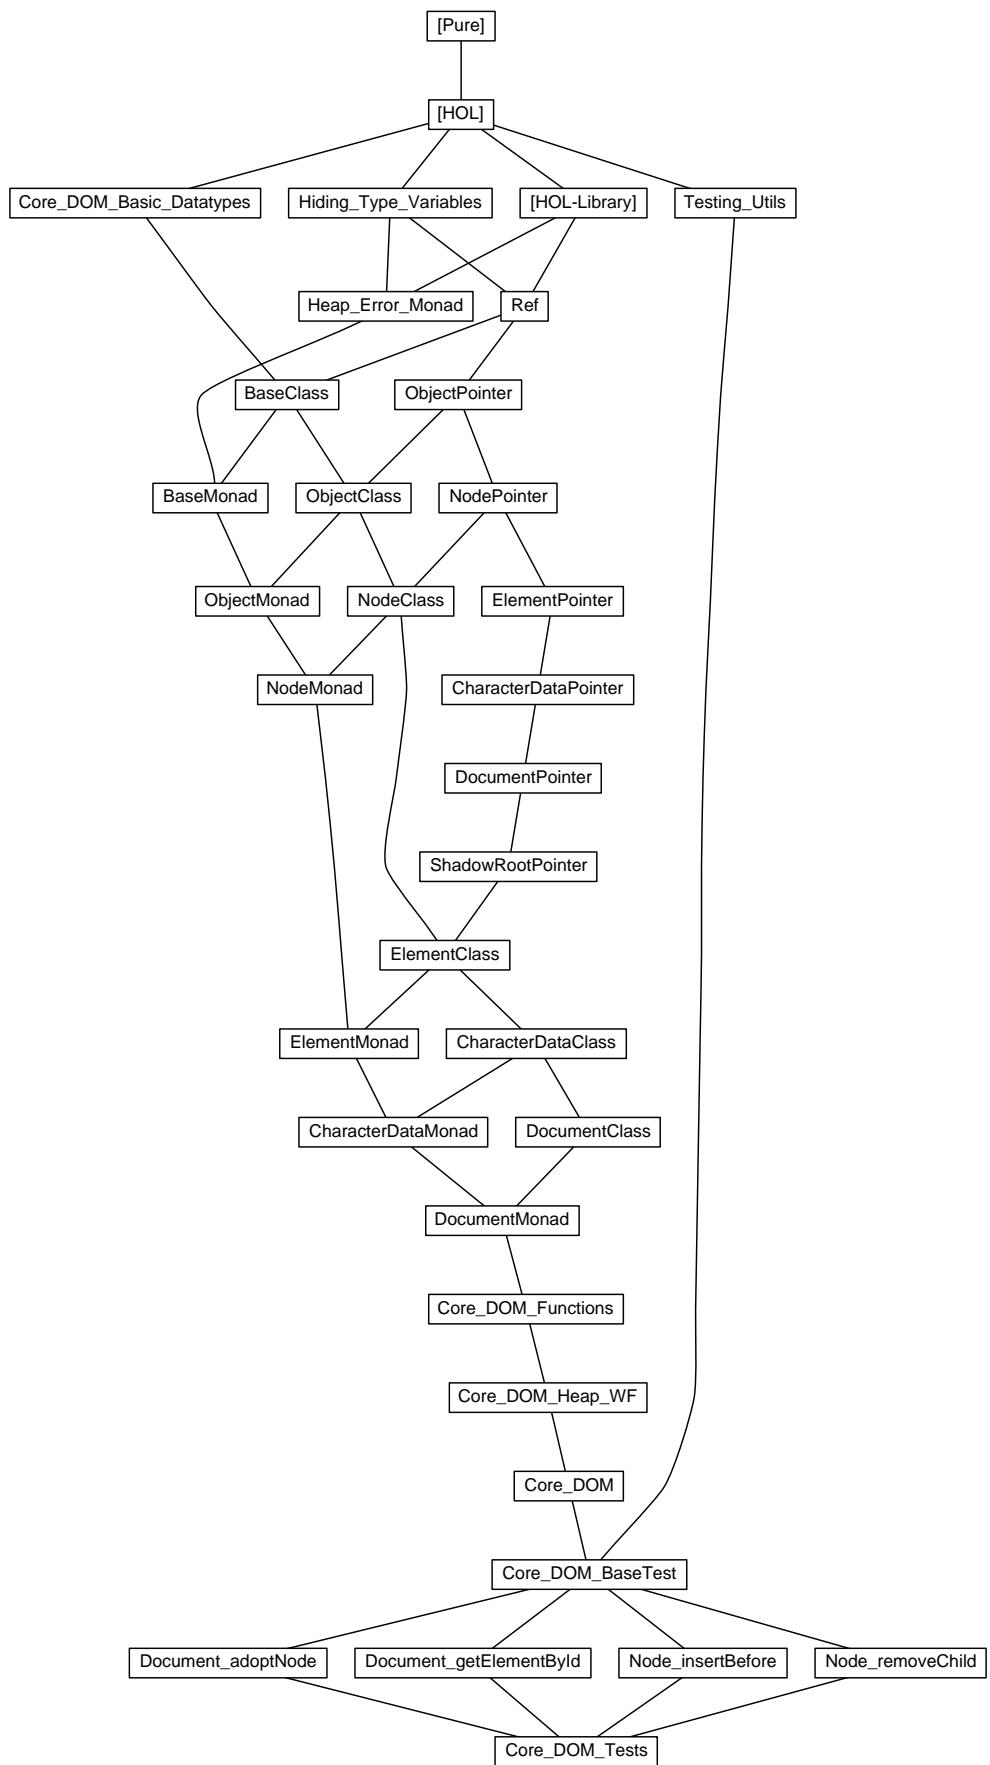

Figure 1.1: The Dependency Graph of the Isabelle Theories.

2 Preliminaries

In this chapter, we introduce the technical preliminaries of our formalization of the core DOM, namely a mechanism for hiding type variables and the heap error monad.

2.1 Hiding Type Variables (Hiding-Type-Variables)

This theory¹ implements a mechanism for declaring default type variables for data types. This comes handy for complex data types with many type variables.

```
theory
  "Hiding_Type_Variables"
imports
  Main
keywords
  "register_default_tvars"
  "update_default_tvars_mode"::thy_decl
begin⟨ML⟩⟨ML⟩⟨ML⟩
```

2.1.1 Introduction

When modelling object-oriented data models in HOL with the goal of preserving *extensibility* (e.g., as described in [3, 7]) one needs to define type constructors with a large number of type variables. This can reduce the readability of the overall formalization. Thus, we use a short-hand notation in cases where the names of the type variables are known from the context. In more detail, this theory sets up both configurable print and parse translations that allows for replacing *all* type variables by $(_)$, e.g., a five-ary constructor $('a, 'b, 'c, 'd, 'e)$ *hide_tvar_foo* can be shortened to $(_)$ *hide_tvar_foo*. The use of this shorthand in output (printing) and input (parsing) is, on a per-type basis, user-configurable using the top-level commands *register_default_tvars* (for registering the names of the default type variables and the print/parse mode) and *update_default_tvars_mode* (for changing the print/parse mode dynamically).

The input also supports short-hands for declaring default sorts (e.g., $(_ :: linorder)$ specifies that all default variables need to be instances of the sort (type class) *linorder* and short-hands of overriding a suffice (or prefix) of the default type variables. For example, $('state) hide_tvar_foo _.$ is a short-hand for $('a, 'b, 'c, 'd, 'state) hide_tvar_foo$. In this document, we omit the implementation details (we refer the interested reader to theory file) and continue directly with a few examples.

2.1.2 Example

Given the following type definition:

```
datatype ('a, 'b) hide_tvar_foobar = hide_tvar_foo 'a | hide_tvar_bar 'b
type_synonym ('a, 'b, 'c, 'd) hide_tvar_baz = "('a + 'b, 'a × 'b) hide_tvar_foobar"
```

We can register default values for the type variables for the abstract data type as well as the type synonym:

```
register_default_tvars "('alpha, 'beta) hide_tvar_foobar" (print_all,parse)
register_default_tvars "('alpha, 'beta, 'gamma, 'delta) hide_tvar_baz" (print_all,parse)
```

This allows us to write

```
definition hide_tvar_f::"(_ hide_tvar_foobar ⇒ (_ hide_tvar_foobar ⇒ (_ hide_tvar_foobar"
  where "hide_tvar_f a b = a"
definition hide_tvar_g::"(_ hide_tvar_baz ⇒ (_ hide_tvar_baz ⇒ (_ hide_tvar_baz"
  where "hide_tvar_g a b = a"
```

¹This theory can be used “stand-alone,” i.e., this theory is not specific to the DOM formalization. The latest version is part of the “Isabelle Hacks” repository: <https://git.logicalhacking.com/adbrucker/isabelle-hacks/>.

Instead of specifying the type variables explicitely. This makes, in particular for type constructors with a large number of type variables, definitions much more concise. This syntax is also used in the output of antiquotations, e.g., $(x::(_)\ hide_tvar_baz \Rightarrow (_)\ hide_tvar_baz \Rightarrow (_)\ hide_tvar_baz) = hide_tvar_g$. Both the print translation and the parse translation can be disabled for each type individually:

```
update_default_tvars_mode "_ hide_tvar_foobar" (noprint,noparse)
update_default_tvars_mode "_ hide_tvar_foobar" (noprint,noparse)
```

Now, Isabelle's interactive output and the antiquotations will show all type variables, e.g., $(x::('a + 'b, 'a \times 'b)\ hide_tvar_foobar \Rightarrow ('a + 'b, 'a \times 'b)\ hide_tvar_foobar \Rightarrow ('a + 'b, 'a \times 'b)\ hide_tvar_foobar) = hide_tvar_g$.

```
end
```

2.2 The Heap Error Monad (Heap_Error.Monad)

In this theory, we define a heap and error monad for modeling exceptions. This allows us to define composite methods similar to stateful programming in Haskell, but also to stay close to the official DOM specification.

```
theory
  Heap_Error.Monad
  imports
    Hiding_Type_Variables
    "HOL-Library.Monad_Syntax"
begin
```

2.2.1 The Program Data Type

```
datatype ('heap, 'e, 'result) prog = Prog (the_prog: "'heap \Rightarrow 'e + 'result \times 'heap")
register_default_tvars "('heap, 'e, 'result) prog" (print, parse)
```

2.2.2 Basic Functions

```
definition
  bind :: "(_ , 'result) prog \Rightarrow ('result \Rightarrow (_ , 'result2) prog) \Rightarrow (_ , 'result2) prog"
  where
    "bind f g = Prog (\h. (case (the_prog f) h of Inr (x, h') \Rightarrow (the_prog (g x)) h'

end

```

3 References and Pointers

In this chapter, we introduce a generic type for object-oriented references and typed pointers for each class type defined in the DOM standard.

3.1 References (Ref)

This theory, we introduce a generic reference. All our typed pointers include such a reference, which allows us to distinguish pointers of the same type, but also to iterate over all pointers in a set.

```
theory
  Ref
  imports
    "HOL-Library.Adhoc_Overloading"
    "../preliminaries/Hiding_Type_Variables"
begin

instantiation sum :: (linorder, linorder) linorder
begin
definition less_eq_sum :: "'a + 'b ⇒ 'a + 'b ⇒ bool"
  where
    "less_eq_sum t t' = (case t of
      Inl l ⇒ (case t' of
        Inl l' ⇒ l ≤ l'
        | Inr r' ⇒ True)
      | Inr r ⇒ (case t' of
        Inl l' ⇒ False
        | Inr r' ⇒ r ≤ r'))"
definition less_sum :: "'a + 'b ⇒ 'a + 'b ⇒ bool"
  where
    "less_sum t t' ≡ t ≤ t' ∧ ¬ t' ≤ t"
instance ⟨proof⟩
end

type_synonym ref = nat
consts cast :: 'a

end
```

3.2 Object (ObjectPointer)

In this theory, we introduce the typed pointer for the class Object. This class is the common superclass of our class model.

```
theory ObjectPointer
  imports
    Ref
begin

datatype 'object_ptr object_ptr = Ext 'object_ptr
register_default_tvars "'object_ptr object_ptr"

instantiation object_ptr :: (linorder) linorder
begin
definition less_eq_object_ptr :: "'object_ptr::linorder object_ptr ⇒ 'object_ptr object_ptr ⇒ bool"
  where "less_eq_object_ptr x y ≡ (case x of Ext i ⇒ (case y of Ext j ⇒ i ≤ j))"
```

```

definition less_object_ptr :: "'object_ptr::linorder object_ptr ⇒ 'object_ptr object_ptr ⇒ bool"
  where "less_object_ptr x y ≡ x ≤ y ∧ ¬ y ≤ x"
instance ⟨proof⟩
end

end

```

3.3 Node (NodePointer)

In this theory, we introduce the typed pointers for the class Node.

```

theory NodePointer
imports
  ObjectPointer
begin

datatype 'node_ptr node_ptr = Ext 'node_ptr
register_default_tvars "'node_ptr node_ptr"

type_synonym ('object_ptr, 'node_ptr) object_ptr = "('node_ptr node_ptr + 'object_ptr) object_ptr"
register_default_tvars "('object_ptr, 'node_ptr) object_ptr"

definition cast_node_ptr2object_ptr :: "(_ node_ptr ⇒ (_ object_ptr"
  where
    "cast_node_ptr2object_ptr ptr = object_ptr.Ext (Inl ptr)"

definition cast_object_ptr2node_ptr :: "(_ object_ptr ⇒ (_ node_ptr option"
  where
    "cast_object_ptr2node_ptr object_ptr = (case object_ptr of object_ptr.Ext (Inl node_ptr)
                                              ⇒ Some node_ptr | _ ⇒ None)"

adhoc_overloading cast cast_node_ptr2object_ptr cast_object_ptr2node_ptr

definition is_node_ptr_kind :: "(_ object_ptr ⇒ bool"
  where
    "is_node_ptr_kind ptr = (cast_object_ptr2node_ptr ptr ≠ None)"

instantiation node_ptr :: (linorder) linorder
begin
definition less_eq_node_ptr :: "(_::linorder) node_ptr ⇒ (_ node_ptr ⇒ bool"
  where "less_eq_node_ptr x y ≡ (case x of Ext i ⇒ (case y of Ext j ⇒ i ≤ j))"
definition less_node_ptr :: "(_::linorder) node_ptr ⇒ (_ node_ptr ⇒ bool"
  where "less_node_ptr x y ≡ x ≤ y ∧ ¬ y ≤ x"
instance
  ⟨proof⟩
end

4 Classes

In this chapter, we introduce the classes of our DOM model. The definition of the class types follows closely the one of the pointer types. Instead of datatypes, we use records for our classes. a generic type for object-oriented references and typed pointers for each class type defined in the DOM standard.

4.1 The Class Infrastructure (BaseClass)

In this theory, we introduce the basic infrastructure for our encoding of classes.

```
theory BaseClass
imports
  "HOL-Library.Finite_Map"
  "../pointers/Ref"
  "../Core_DOM_Basic_Datatypes"
begin

named_theorems instances

consts get :: 'a
consts put :: 'a
consts delete :: 'a
```

Overall, the definition of the class types follows closely the one of the pointer types. Instead of datatypes, we use records for our classes. This allows us to, first, make use of record inheritance, which is, in addition to the type synonyms of previous class types, the second place where the inheritance relationship of our types manifest. Second, we get a convenient notation to define classes, in addition to automatically generated getter and setter functions.

Along with our class types, we also develop our heap type, which is a finite map at its core. It is important to note that while the map stores a mapping from *object_ptr* to *Object*, we restrict the type variables of the record extension slot of *Object* in such a way that allows down-casting, but requires a bit of taking-apart and re-assembling of our records before they are stored in the heap.

Throughout the theory files, we will use underscore case to reference pointer types, and camel case for class types.

Every class type contains at least one attribute; nothing. This is used for two purposes: first, the record package does not allow records without any attributes. Second, we will use the getter of nothing later to check whether a class of the correct type could be retrieved, for which we will be able to use our infrastructure regarding the behaviour of getters across different heaps.

```
locale l_type_wf = fixes type_wf :: "'heap ⇒ bool"

locale l_known_ptr = fixes known_ptr :: "'ptr ⇒ bool"

end
```

4.2 Object (ObjectClass)

In this theory, we introduce the definition of the class Object. This class is the common superclass of our class model.

```
theory ObjectClass
imports
  BaseClass
  "../pointers/ObjectPointer"
```

```

begin

record RObject =
  nothing :: unit
register_default_tvars "'Object RObject_ext"
type_synonym 'Object Object = "'Object RObject_scheme"

5 Monadic Object Constructors and Accessors

In this chapter, we introduce the monadic method definitions for the classes of our DOM formalization. Again the overall structure follows the same structure as for the class types and the pointer types.

5.1 The Monad Infrastructure (BaseMonad)

In this theory, we introduce the basic infrastructure for our monadic class encoding.

```

6 The Core DOM

In this chapter, we introduce the formalization of the core DOM, i.e., the most important algorithms for querying or modifying the DOM, as defined in the standard. For more details, we refer the reader to [4].

6.1 Basic Data Types (Core_DOM_Basic_Datatypes)

This theory formalizes the primitive data types used by the DOM standard [1].

```
theory Core_DOM_Basic_Datatypes
imports
  Main
begin

type_synonym USVString = string
```

In the official standard, the type *USVString* corresponds to the set of all possible sequences of Unicode scalar values. As we are not interested in analyzing the specifics of Unicode strings, we just model *USVString* using the standard type *string* of Isabelle/HOL.

```
type_synonym DOMString = string
```

In the official standard, the type *DOMString* corresponds to the set of all possible sequences of code units, commonly interpreted as UTF-16 encoded strings. Again, as we are not interested in analyzing the specifics of Unicode strings, we just model *DOMString* using the standard type *string* of Isabelle/HOL.

```
type_synonym doctype = DOMString
```

```
Examples definition html :: doctype
  where "html = ''<!DOCTYPE html>'''"
```

```
hide_const id
```

This dummy locale is used to create scoped definitions by using global interpretations and defines.

```
locale l_dummy
begin
```

6.2 Querying and Modifying the DOM (Core_DOM_Functions)

In this theory, we are formalizing the functions for querying and modifying the DOM.

```
theory Core_DOM_Functions
imports
  "monads/DocumentMonad"
begin
```

If we do not declare *show_variants*, then all abbreviations that contain constants that are overloaded by using *adhoc_overloading* get immediately unfolded.

```
declare [[show_variants]]
```

6.2.1 Various Functions

```
lemma insort_split: "x ∈ set (insort y xs) ↔ (x = y ∨ x ∈ set xs)"
  ⟨proof⟩

lemma concat_map_distinct:
  "distinct (concat (map f xs)) ⟹ y ∈ set (concat (map f xs)) ⟹ ∃!x ∈ set xs. y ∈ set (f x)"
```

```

⟨proof⟩

lemma concat_map_all_distinct: "distinct (concat (map f xs)) ⟹ x ∈ set xs ⟹ distinct (f x)"
⟨proof⟩

lemma distinct_concat_map_I:
assumes "distinct xs"
and "⋀x. x ∈ set xs ⟹ distinct (f x)"
and "⋀x y. x ∈ set xs ⟹ y ∈ set xs ⟹ x ≠ y ⟹ (set (f x)) ∩ (set (f y)) = {}"
shows "distinct (concat ((map f xs)))"
⟨proof⟩

lemma distinct_concat_map_E:
assumes "distinct (concat ((map f xs)))"
shows "⋀x y. x ∈ set xs ⟹ y ∈ set xs ⟹ x ≠ y ⟹ (set (f x)) ∩ (set (f y)) = {}"
and "⋀x. x ∈ set xs ⟹ distinct (f x)"
⟨proof⟩

lemma bind_is_OK_E3 [elim]:
assumes "h ⊢ ok (f ≈ g)" and "pure f h"
obtains x where "h ⊢ f →_r x" and "h ⊢ ok (g x)"
⟨proof⟩

```

6.4 The Core DOM (Core_DOM)

This theory is the main entry point of our formalization of the core DOM.

```
theory Core_DOM
imports
  "Core_DOM_Heap_WF"
begin

end
```

7 Test Suite

In this chapter, we present the formalized compliance test cases for the core DOM. As our formalization is executable, we can (symbolically) execute the test cases on top of our model. Executing these test cases successfully shows that our model is compliant to the official DOM standard. As future work, we plan to generate test cases from our formal model (e.g., using [6, 8]) to improve the quality of the official compliance test suite. For more details on the relation of test and proof in the context of web standards, we refer the reader to [5].

7.1 Common Test Setup (Core_DOM_BaseTest)

This theory provides the common test setup that is used by all formalized test cases.

```
theory Core_DOM_BaseTest
imports
  "../../Core_DOM"
begin

definition "assert_throws e p = do {
  h ← get_heap;
  (if (h ⊢ p →e e) then return () else error AssertException)
}''"

7.5 Testing removeChild (Node.removeChild)

This theory contains the test cases for removeChild.

```

theory Node_removeChild
imports
  "Core_DOM_BaseTest"
begin

definition Node_removeChild_heap :: "(unit, unit, unit, unit, unit, unit, unit, unit, unit, unit) heap"
where

```

```

"Node_removeChild_heap = create_heap [(cast (document_ptr.Ref 1), cast (create_document_obj html (Some
(cast (element_ptr.Ref 1)))) []),
  (cast (element_ptr.Ref 1), cast (create_element_obj ''html'' [cast (element_ptr.Ref 2), cast (element_ptr.Ref
7)] fmempty None)),
  (cast (element_ptr.Ref 2), cast (create_element_obj ''head'' [cast (element_ptr.Ref 3), cast (element_ptr.Ref
4), cast (element_ptr.Ref 5), cast (element_ptr.Ref 6)] fmempty None)),
  (cast (element_ptr.Ref 3), cast (create_element_obj ''title'' [cast (character_data_ptr.Ref 1)] fmempty
None)),
  (cast (character_data_ptr.Ref 1), cast (create_character_data_obj ''Node.removeChild'')),
  (cast (element_ptr.Ref 4), cast (create_element_obj ''script'' [] (fmap_of_list [(''src'', ''/resources/testhan
None))),
  (cast (element_ptr.Ref 5), cast (create_element_obj ''script'' [] (fmap_of_list [(''src'', ''/resources/testhan
None))),
  (cast (element_ptr.Ref 6), cast (create_element_obj ''script'' [] (fmap_of_list [(''src'', ''creators.js'')])))
None)),
  (cast (element_ptr.Ref 7), cast (create_element_obj ''body'' [cast (element_ptr.Ref 8), cast (element_ptr.Ref
9), cast (element_ptr.Ref 10)] fmempty None)),
  (cast (element_ptr.Ref 8), cast (create_element_obj ''div'' [] (fmap_of_list [(''id'', ''log'')] None)),
  (cast (element_ptr.Ref 9), cast (create_element_obj ''iframe'' [] (fmap_of_list [(''src'', ''about:blank'')])))
None)),
  (cast (element_ptr.Ref 10), cast (create_element_obj ''script'' [cast (character_data_ptr.Ref 2)] fmempty
None)),
  (cast (character_data_ptr.Ref 2), cast (create_character_data_obj ''%3C%3Cscript%3E%''))]

definition document :: "(unit, unit, unit, unit, unit, unit) object_ptr option" where "document = Some (cast

⟨proof⟩

```

end

7.6 Core DOM Test Cases (Core_DOM_Tests)

This theory aggregates the individual test cases for the core DOM.

```

theory Core_DOM_Tests
imports
  "tests/Document_adoptNode"
  "tests/Document_getElementById"

```

```
"tests/Node_insertBefore"  
"tests/Node_removeChild"  
begin  
end
```
